

CARBON DATING FLAWS

Lanthano

9/12/2022

Carbon dating is simple: you look at something, say, a rock. Measure the carbon inside it, and with that knowledge you can deduce how old the item is. However, if someone in the future tells you that carbon dating proves that the earth is 4 billion years old and disproves the Bible, try not to laugh at them.

See: [https://answersingenesis.org/search/?q=carbon dating](https://answersingenesis.org/search/?q=carbon+dating)

stable & unstable atoms (figure 1)

Radiometric dating is based on a simple fact about atoms. If an atom has too many neutrons in its nucleus (blue circle below), it is unstable and will change into a stable form. To date a sample, scientists calculate how much time would be required for the unstable atoms in the sample to change into a stable form.

For example, most carbon atoms are stable because they have only six or seven neutrons in their nuclei (carbon-12 and carbon-13, above). But some carbon atoms have too many neutrons and are unstable (carbon-14).

While carbon dating is the most well-known method of dating, it is definitely not the only, evolutionary scientists like to use tree rings, ice layers, radiometric dating, and other such things to determine the age of something. However, each of the methods I just stated have critical flaws. (see figure 2)

Carbon dating is worthless for an evolutionist. The half-life of Carbon-14 is about 5,700 years. The most Carbon-14 dating could be used for is about 50,000 years, and this is worthless for the evolution side of things, where the earth is “supposedly” 4.5 billion years old.

Rocks supposedly millions of years old, still have been found to have carbon-14 in them! How? For an evolutionist, it is impossible to know.

“Many people assume that rocks are dated at “millions of years” based on radiocarbon (carbon-14) dating. But that’s not the case. The reason is simple. Carbon-14 can yield dates of only “thousands of years” before it all breaks down.”-<https://answersingenesis.org/geology/carbon-14/carbon-14-dating/>

Knowing this, the age must be assumed.

HOW IT WORKS

CARBON-14 IS CREATED: When cosmic rays bombard the earth's atmosphere, they produce neutrons. These excited neutrons then collide with nitrogen atoms in the atmosphere, changing them into radioactive carbon-14 atoms. **CARBON-14 IS ABSORBED** (Figure 1b): Plants absorb this carbon-14 during photosynthesis. When animals eat the plants, the carbon-14 enters their bodies. The carbon-14 in their bodies breaks down to nitrogen-14 and escapes at the same rate as new carbon-14 is added. So the level of carbon-14 remains stable.

CARBON-14 IS DEPLETED: When an animal dies the carbon-14 continues to break down to nitrogen-14 and escapes, while no new carbon-14 is added. By comparing the surviving amount of carbon-14 to the original amount, scientists can calculate how long ago the animal died.

While carbon-14 dating is more reliable than some other methods of age dating. It still is not a tool evolutionist should be claiming to have on their side. Due to its half-life being around 6,000 years, and the longest age it being useful for around 50,000 to 80,000 years.. (Which is nowhere near the millions of years the evolutionist's claim.)

Carbon-14 dating yields dates than seem to point toward a young earth.
